Economical and Environment-Friendly

Advantages of Sealed Spherical Roller Bearings by ZKL

Double-row spherical roller bearings by ZKL are popular and widespread across all engineering branches. They consist of two rows of spherical rollers with a common spherical track in the outer ring. This structure allows for mutual tipping of the bearing rings. Thus they can simultaneously transfer considerable radial and axial loads in both directions. The bearings are made with a cylindrical and a tapered bore. These bearings are suitable for applications with high loads acting on them where tipping has to be ensured so as the bearings may eliminate movement and misalignment of shafts.

Sealed double-row spherical roller bearings by ZKL have the same inside structure as their open counterparts.

Reduced Maintenance Need

Sealed double-row spherical roller bearings by ZKL are ready for immediate use. They are lubricated by the manufacturer with high-standard grease. Bearing contamination is prevented by contact seal on both sides of the bearing. The lubricant needs neither replenishment nor change and so the bearings are virtually maintenance-free in many applications.

Increased Availability and Reliability

Maintenance of clean bearing inside is necessary for its long-term function - service life - in the machine. Even very small particles can negatively affect the life of the bearing. Use of sealed double-row spherical roller bearings can successfully prevent penetration of impermissible humidity and impurities.

Reduced Lubricant Consumption

The contact seals on both sides of the bearing assure that the bearing will always keep sufficient grease. In many cases the life of the lubricant is longer than the life of the bearing (or application). For that reason the bearings do not need further lubrication.

Applications of Sealed Spherical Roller Bearings

Sealed spherical roller bearings are mainly used in applications with increased contamination and humidity of the surroundings. Where outer seal cannot be applied or in the case of strong contamination "multi-barrier" seal should be used.

Environment-Friendly

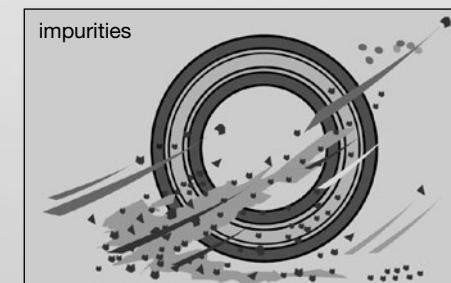

Users of sealed double-row spherical roller bearings can reduce their costs of purchase and disposal of grease. Another important factor is that these bearings are able to reduce environmental impact of the machine during its operation time.

Increased Efficiency in Various Industrial Branches

Reliability

Sealed double-row spherical roller bearings by ZKL provide a high level of reliability in most demanding applications. The contact seal prevents lubricant leaks and protects the bearing against impurities in its surroundings both during handling and assembly and mainly during the machine operation.

Lubrication

Bearings used for standard operation temperatures and speeds are lubricated with grease ZKL LV 2 EP (reinforced with lithium soap). Greases are mainly designed for lubrication of rolling bearings working under increased pressures and exposed to high dynamic stress.

Protection

The bearings are provided with contact seals on both sides. The seals are made of NBR, HNBR and - for high temperatures - FKM rubber. The seal is also reinforced with steel sheet metal.

Industrial branches:

- Metallurgy
- Mining
- Civil engineering
- Industrial transmissions
- Textile industry
- Energy generation
- Railways
- Material handling

Typical customer requirements:

- Long service intervals
- High load-bearing capacity of bearings
- Tipping option
- Minimum maintenance
- Low operation costs
- Minimum unplanned downtimes
- Availability
- Technical support
- Environment-friendly

Bearing Size Specification

Bearing Durability

The application of calculation of basic durability L_{10} as a criterion of bearing performance has proved to be reliable for many years. This calculation is connected with 90% reliability in the case of application of the commonly used high-standard materials, top-quality technological craftsmanship and normal operation conditions.

Nevertheless for many applications the calculation has become desirable to be performed by another reliability level or for more accurate conditions of lubrication and contamination. Application of modern high-standard bearing steel has revealed that under favourable operation conditions and lower contact tensions than the specified limit tension and if the limit fatigue tension of bearing steel is not exceeded then it is possible to achieve higher durability than L_{10} . On the other hand under unfavourable operation conditions the bearing durability may be lower than L_{10} .

The system approach of fatigue durability was used for development of the methodology for calculation of modified durability according to ZKL. Effect on durability of the system (bearing) is described in the following text and considers the effect of dispersion and interactions of mutually linked factors on overall life. These factors are manifested by increased contact tension in the contact points which result in decreased life.

These factors are used in the modified durability equation.

$$L_m = a_1 * a_{ZKL} * L_{10}$$

Equation:

$$L_m = a_1 * a_{ZKL} * \left(\frac{C}{P} \right)^{\frac{10}{3}}$$

If the speed is constant durability may be expressed in operation hours with the following equation:

$$L_{mh} = a_1 * a_{23} * \frac{1000000}{60 * n} * \left(\frac{C}{P} \right)^{\frac{10}{3}}$$

Where:

L_m – durability adapted for reliability (100 - n) % and other than usual operation conditions

L_{mh} – durability adapted for reliability (100 - n) % and other than usual operation conditions

L_{10} – basic durability

a_1 – reliability coefficient for reliability other than 90 % (see table 1)

a_{ZKL} – coefficient of material, lubricant, technology of manufacture and operation conditions (see diagram 1)

C – basic dynamic load-bearing capacity [kN]

P – equivalent dynamic load of bearing [kN]

Table 1

Values of coefficient a_1		
Reliability (%)	L_n	a_1
90	L_{10}	1
95	L_5	0,64
96	L_4	0,55
97	L_3	0,47
98	L_2	0,37
99	L_1	0,25

Equivalent Dynamic Load P

To be able to calculate basic durability with the relevant equation you need to recalculate the actually acting load on equivalent load, i.e. implied steady load meeting the conditions valid for the basic dynamic load-bearing capacity and equally affecting bearing durability as the actual load. For correct calculation of this load you need most accurate knowledge of the external forces acting on the bearing.

$$\begin{aligned} P &= F_r + Y_1 F_a \quad \text{pro } F_a/F_r \leq e \text{ [kN]} \\ P &= 0,67 F_r + Y_2 F_a \quad \text{pro } F_a/F_r > e \text{ [kN]} \end{aligned}$$

Where:

- P – equivalent dynamic load
- F_r – radial load (kN)
- F_a – axial load (kN)
- Y – axial load coefficient
- X – radial load coefficient

The values of coefficients e , Y_1 and Y_2 for the individual bearing types are shown in the table section of this document below.

Comparison of Durability of Sealed Double-Row Spherical Roller Bearing with its Open Variant

Higher durability of the sealed double-row spherical roller bearings in comparison to their open counterparts can be easily demonstrated by the durability calculation. We will therefore compare the sealed double-row spherical roller bearing B2-2224-2RSR TN with its open counterpart 22224EW33MH.

Dynamic load-bearing capacity C_r and limit fatigue load P_u of both bearings are the same.

$$C_r = 608 \text{ kN}$$

$$P_u = 81 \text{ kN}$$

Operating conditions of the bearings are:

- Equivalent dynamic load $P = 55 \text{ kN}$
- Viscosity ratio $\kappa = 2$
- Contamination factor $e_c = 0.7$ for the sealed bearing (☞ table 2)
- Contamination factor $e_c = 0.4$ for the open bearing (☞ table 2)

Durability calculation for the sealed variant:

Enter $e_c \times (P_u / P) = 0.7 \times (81 / 55) = 1.03$ to the horizontal scale in (☞ Diagram 1). Move vertically towards the intersection with curve $\kappa = 2$ to get $a_{ZKL} = 31$.

$$L_{10m} = a_{ZKL} \times (C / P) 10 / 3 = 31 \times (608 / 55) 10 / 3$$

$$L_{10m} = 93,289 \text{ million revolutions}$$

Durability calculation for the open variant:

Enter $e_c \times (P_u / P) = 0.4 \times (81 / 55) = 0.58$ to the horizontal scale in (☞ Diagram 1). Move vertically towards the intersection with curve $\kappa = 2$ to get $a_{ZKL} = 7$.

$$L_{10m} = a_{ZKL} \times (C / P) 10 / 3 = 7 \times (608 / 55) 10 / 3$$

$$L_{10m} = 21,065 \text{ million revolutions}$$

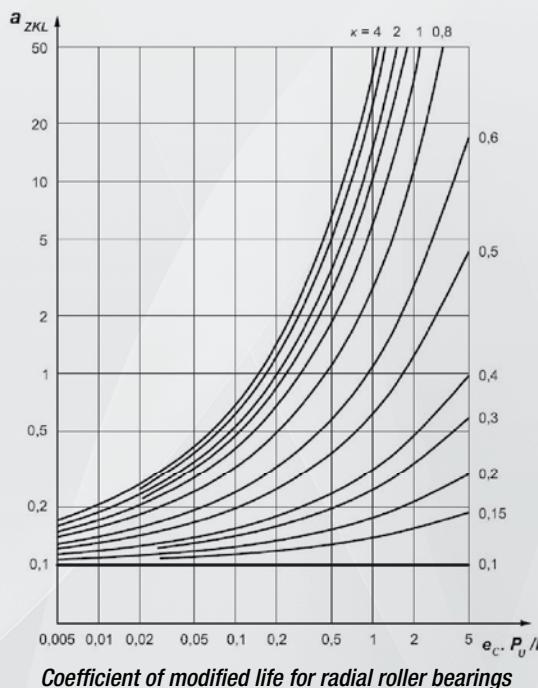

In this particular case the durability ratio between equivalent sealed and open bearing is $93,289 / 21,065 = 4.4$. It can then be said that the durability of the sealed bearing is more than quadruple in comparison to its open variant.

Table 2

Contamination level	e_c	
	$D_{pw} < 100 \text{ mm}$	$D_{pw} \geq 100 \text{ mm}$
Extremely clean Particle size in the order of lubricating film thickness, Laboratory conditions	1	1
Highly clean Oil filtered through a very fine filter, typical conditions for a bearing with plastic housing and lifetime lubricant filling	0.8 až 0.6	0.9 až 0.8
Normally clean Oil filtered through a fine filter, typical conditions for a bearing with metal-sheet housing and lifetime lubricant filling	0.6 až 0.5	0.8 až 0.6
Mild contamination	0.5 až 0.3	0.6 až 0.4
Minor contamination in lubricant		
Typical contamination Typical bearing conditions without integrated bearing glands, particles causing wear enter bearing from vicinity	0.3 až 0.1	0.4 až 0.2
Strong contamination The bearing environment is strongly contaminated, bearing housing with insufficient bearing glands	0.1 až 0	0.1 až 0
Very strong contamination	0	0

Diagram 1

Bearing Application

Connection Size

A part of the portfolio of sealed double-row spherical roller bearings by ZKL is wider than their open variants.

These bearings thus cannot replace the standard open variant without adaptation of the components immediately adjacent to the bearing.

Thanks to the bearing surface of the inner race flange for the seal, which is tapered, diameter d_2 (☞ product table) is reduced in comparison to the open variant.

When determining connection diameter d_a the diameter d_2 of the sealed variant must be considered (☞ figure 1).

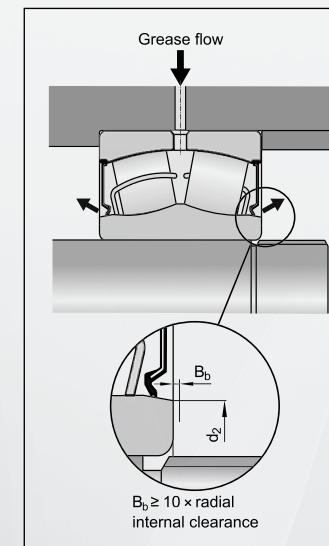

Figure 1

Bearing Space

Most sealed double-row spherical roller bearings by ZKL are designed with the seal inside the side front plane, with a slight overlap in some bearings. It is necessary to assure that nothing of the shaft or bearing body is in contact with the seal during operation.

For applications where additional lubrication is needed the axial space must be big enough (☞ figure 1), for the grease to be able to pass through the seal. The axial space should be at least 10times bigger than the inner radial clearance of the bearing.

ZKL Three Barrier Protection

ZKL three barrier protection includes:

1. Sealed two-row spherical roller bearing,
2. Bearing body filled in 70 to 90 % with grease,
3. External labyrinth seal ( figure 2), representing a very efficient solution.

Applications with a standard open bearing and contact seal in the bearing body can generate higher friction than in the case of use of the ZKL three barrier protection. The use of the sealed double-row spherical roller bearing also means that the grease used as the bearing body fill and lubricant for the labyrinth seal is independent on the bearing lubrication. The location must provide sufficient axial space in the bearing body for the axially loose bearing for the displacement to be allowed.

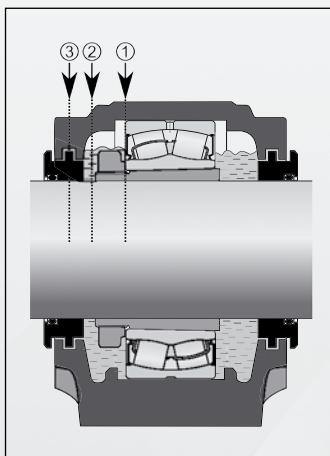

Figure 2

Lubrication

Sealed double-row spherical roller bearings in the product table below feature a perimeter groove in the outer race with three lubrication holes as a standard (W33).

When lubricating the bearing the lubricant must be replenished slowly until the new lubricant begins to go out under the seal. High pressures during lubrication must be prevented to avoid damage to the seal.

Re-Lubrication Intervals

Re-lubrication intervals should be the same for sealed as well as standard bearings. The inner structure of the sealed spherical roller bearing by ZKL is able to hold considerable axial forces but if $F_a/F_r > e$

( product table) ZKL recommends increasing the re-lubrication frequency.

Grease Quantity for Re-Lubrication

The required quantity of grease for re-lubrication is calculated with the help of the following formula: $Q = 0.0015 \times D \times B$

Where:

Q – quantity of grease for replenishment, [g]

D – outer diameter of bearing, [mm]

B – bearing width, [mm]

Rules of No-Maintenance Operation

- Operation for 8 hours/day (not always in full use)
- Normal operation conditions
- Shaft in horizontal position

The bearing may be considered low-maintenance if:

- The speed is 50% lower than the limit speed
- Operation temperature does not exceed 70 °C (160 °F)

Assembly and Disassembly

Assembly

It is important to prevent high tip of the bearing during assembly of sealed double-row spherical roller bearings. High tip of the outer bearing race in relation to the inner race may result in contact of a spherical roller face or the cage with the seal which may cause the seal to get loose or damaged.

Bearings with Cylindrical Bore

Sealed double-row spherical roller bearings with a cylindrical bore may be heated with induction heater and hot assembled or cold pressed onto the shaft.

ZKL does not recommend heating sealed bearings to temperatures exceeding 80 °C (175 °F). If a higher temperature is required it should not exceed the limit temperature of the seal or the lubricant.

ZKL does not recommend use of heating plates either, for this might result in direct contact

of the plate with the seal which is undesirable. To assure the appropriate distance a back plate must be used.

ZKL recommends locknuts with a lower diameter on one side for axial locking of sealed double-row spherical roller bearings, however with assurance of axial free space between the nut and the seal for the lubricant to be able to go off during re-lubrication (*figure 3*).

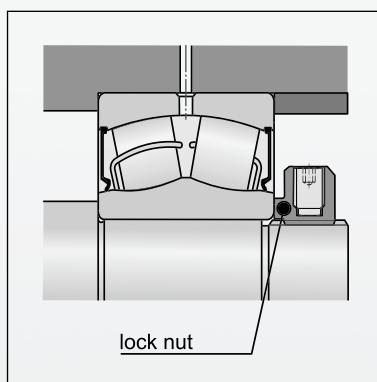

Figure 3

Another alternative is a standard locknut with a back plate. In this case a distance ring must be placed between the inner race of the bearing and the nut with a width and outer diameter not preventing the lubricant from going out during re-lubrication (*figure 4*).

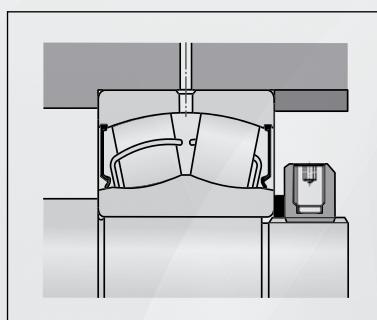

Figure 4

Bearings with Tapered Bore

When assembling sealed double-row spherical roller bearings with a tapered bore it is not possible to measure radial clearance of the bearing with gap gauge. ZKL recommends the traditional method using the hook wrench and angle measurement.

The pressurised oil method is beneficial with larger bearings.

Recommended values of radial clearance and axial displacement reduction are shown in (*table 3*). The minimum values of radial clearance reduction shown in the table are applicable to bearings with normal radial clearance close to the bottom limit of the required clearance range. For bearings with clearances C3 and C4 a value of radial clearance reduction close to the maximum recommended value is recommended.

Assembly of double-row spherical roller bearings with a tapered bore

Table 3

Assembly on Clamping Case

Clamping case facilitates assembly and disassembly. This is generally the simplest arrangement (*figure 5a*)

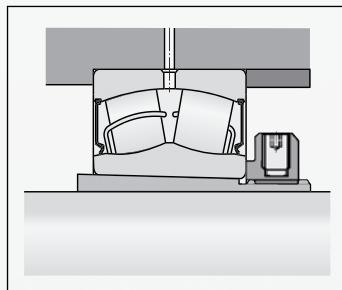

Figure 5a

A folding case is more appropriate for bearings requiring axial positioning (☞ figure 5b)

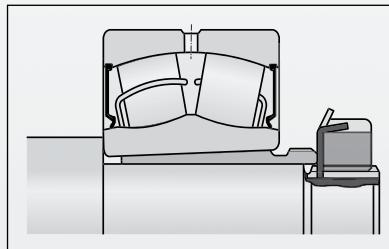

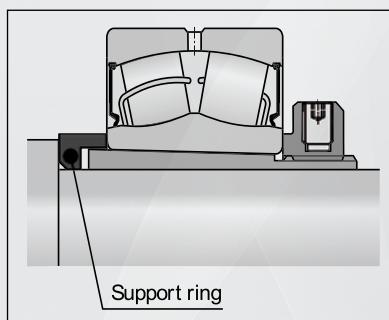

Figure 5b

Nevertheless even with the clamping case the bearings can be positioned axially with a support ring (☞ figure 5c)

Some bearings are made with a relatively small radial space for the support ring and so big axial forces acting on these bearings are not desirable.

Note: Bore radius $r_{s\min}$ of sealed spherical roller bearings with tapper bore is different from the bearings with cylindrical bore.

Figure 5c

Disassembly

Bearing disassembly is described in the main catalogue of ZKL "Roller Bearings", ZKL Publication 3/13/ CZ on ☞ page 147.

If the bearings are to be reused after disassembly their seal must be intact.

Bearings – General Data

All ZKL sealed double-row spherical roller bearings are made in the NEW FORCE quality.

Cylindrical or Tapered Bore

ZKL sealed double-row spherical roller bearings are made either with a cylindrical or with a tapered bore. The taper of the tapered bore is 1:12.

Peripheral Groove with Three Lubrication Holes

For easier re-lubrication all ZKL sealed double-row spherical roller bearings feature a perimeter groove in the outer race with three lubrication holes as a standard

Table 4

Dimensions

The main dimensions of ZKL sealed double-row spherical roller bearings comply with ISO 15:1998 standard, except for B2 bearings the bearing width being larger.

Inner Radial Clearance

Standard sealed spherical roller bearings by ZKL are made with normal inner radial clearance. The bearings are also available with increased inner clearances, C3 and C4. Some dimensions are also available with lower than normal C2 radial clearance.

Inner radial clearances comply with ISO 5753:1991 standard, their values being specified in ([Table 4](#)). The tabulated values apply to bearings before assembly.

Tip

The structure of sealed spherical roller bearings is designed to allow for tipping. Thus the bearing is able to eliminate angular deflection of the shaft in relation to the bearing body without any negative impact on the load-bearing capacity of the bearing.

Under operation conditions where the deflection is constant in relation to the outer race ZKL sealed spherical roller bearings are able to eliminate misalignment of the shaft in relation to the body up to about 0.5°. Unless the above value is exceeded the misalignment does not negatively affect efficiency of the seal.

If the misalignment in relation to the outer race of the bearing is not constant ([figure 6](#)) then friction inside the bearing increases and that is why the misalignment of the inner in relation to the outer race should not exceed a couple of tenths of a degree.

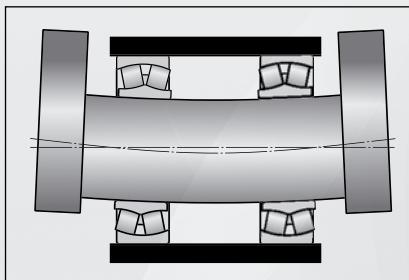

Figure 6

Effect of Operation Temperature on Bearing Materials

Operation temperature of sealed double-row spherical roller bearings must not exceed the limit temperatures for the seal and the grease.

- Bearings with suffix 2RSN TM should not be used at operation temperatures above +90 deg. C (194 deg. F).
- Bearings with suffix 2RSH TM or 2RSF TM should not be used at operation temperatures above +110 deg. C (230 deg. F).

- As for the possibility of use of sealed double-row spherical roller bearings at higher temperatures please contact the technical department of ZKL.

Axial Load-Bearing Capacity of Bearings

Thanks to their inner structure the sealed spherical roller bearings by ZKL are able to hold considerable axial forces acting on the bearing, but if $F_a/F_r > e$ ([product table](#)) it is recommended to increase the re-lubrication frequency.

Speed

The speed of the sealed double-row spherical roller bearings is limited by friction generated by the contact seal. That is why just limit speeds are shown in the product table. Limit speeds of sealed double-row spherical roller bearings are lower than limits speeds of unsealed bearings ([product table](#)).

Sealing Materials

The sealing material type depends on the bearing size. The following materials have been used for the seals:

- Acrylonitrile-butadiene rubber (NBR), identified with suffix N
- Hydrogenated acrylonitrile-butadiene rubber (HNBR), identified with suffix H
- Fluor-elastomere (FKM), identified with suffix F

Additional Data

For a practical listing of the portfolio of sealed bearings including their individual structural differences and re-lubrication data see the ([product table](#)).

Radiiuses of the bearing bores r_{smin} are shown in the product table and apply to the bearings with a cylindrical bore. The corresponding values for the bearings with a tapered bore are shown in ([table 5](#)).

Assembly radius in the bearing bore For cylindrical and tapered bores	
Cylindrical bore	Tapered bore
r_{smin}	r_{smin}
1.0 to 1.1	0.6
1.5 to 2.0	1.0
2.1 to 3.0	1.1
4.0	1.5
5.0	2.0
6.0	3.0

Table 5

Attention!

Safety Precautions for Rubber Fluoride (FKM)

Fluoride rubber is very stable and harmless up to operation temperature +200 deg. C. Nevertheless, if the seal is exposed to a temperature higher than 300 deg. C, such as fire or cutting burner flame, the fluoride rubber may produce dangerous evaporation. These vapours may be harmful to human health if inhaled and also eye contact should be avoided.

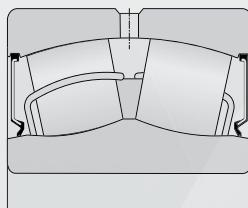

If the seal has ever been exposed to these high temperatures skin contact should be avoided even after the seal has been cooled down. If handling a sealed bearing after its exposure to high temperatures, for example during disassembly, is required, then the following precautions should be observed:

- Always use protective goggles, gloves and a suitable respirator.
- Place the seal in an airtight package with a symbol or text warning of cauterisation.

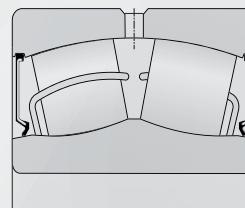

In the case of contact with the seal wash hands with plenty of water with soap, rinse the eyes with plenty of water and seek medical attention immediately.

The user is liable for proper use during operation and for lawful disposal. ZKL does not take responsibility for handling of fluoride rubber during transport.

Identification

ZKL uses two types of identification of sealed double-row spherical roller bearings. The first identification type for sealed bearings is based on the ISO dimension standard. The second identification type is used for bearings wider than those specified in the ISO standard.

Wider than ISO standard bearings

B2 – 2212 – 2RSN C3 TN

Basic structure

Double-row spherical roller bearing

Wider bearing

The first two digits identify the dimensional series, the last two multiplied with 5 identify the bore diameter

Seal

2RSN

Acrylonitrile-butadiene rubber (NBR), sealing on both sides with the option of re-lubrication via the outer race

2RSH

Hydrogenated acrylonitrile-butadiene rubber (HNBR), sealing on both sides with the option of re-lubrication via the outer race

2RSF

Fluor-elastomere (FKM), sealing on both sides with the option of re-lubrication via the outer race

Radial clearance

C2

Inner radial clearance lower than normal

C3

Inner radial clearance higher than normal

C4

Inner radial clearance higher than C3

Lubricant

TM

Grease up to 110 °C

TN

Grease up to 150 °C

TH

Grease up to 200 °C

Bearings with main dimensions pursuant to ISO standard

23048 – 2RSN C3 TN

Basic structure

Five standard digits of basic identification for unsealed bearings

Seal

2RSN

Acrylonitrile-butadiene rubber (NBR), sealing on both sides with the option of re-lubrication via the outer race

2RSH

Hydrogenated acrylonitrile-butadiene rubber (HNBR), sealing on both sides with the option of re-lubrication via the outer race

2RSF

Fluor-elastomere (FKM), sealing on both sides with the option of re-lubrication via the outer race

Radial clearance

C2

Inner radial clearance lower than normal

C3

Inner radial clearance higher than normal

C4

Inner radial clearance higher than C3

Lubricant

TM

Grease up to 110 °C

TN

Grease up to 150 °C

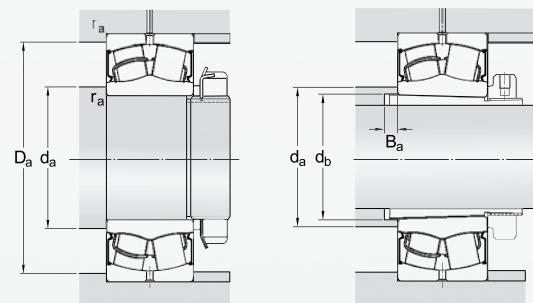

TH

Grease up to 200 °C
